1 Overview

In this project, the goal was to locate and estimate the orbit of two GPS satellites, GPS 10 and GPS 32, given the following variables:

- Pseudorange Data between the GNSS Satellite and three chosen Ground Stations.
- The Earth-Centered, Earth-Fixed Coordinates of the three chosen Ground Stations.
- A chosen date and time between January and October of 2019.

2 Work Done

2.1 Choosing the Ground Sites and the Date

2.1.1 Ground Sites

The following ground sites were chosen for this Project:

- GODE (Greenbelt, Maryland)
- NJTR (Trenton, New Jersey)
- LYCO (Middle of Pennsylvania)

September, 29, 2019 was chosen as the observation date for both GNSS satellite. We set t_1 to 20:00 UTC Time for both satellites, as this was the time where the GNSS satellites were visible to all three of the ground stations. The end time, occurred twelve hours after t_1 . The date was chosen at the end of the allowable date range (January to October 2019). The idea behind choosing such a recent date was to improve the accuracy of our results by using the most recent data. The orbits of satellites change with time due to Perturbations and Drag. It is believed that the most recent data will give us the most recent orbital data which will be closest to the actual, current orbital elements of the GNSS satellite.

2.2 Trilateration

Trilateration was used by creating a function following the steps outlined in the book. There were issues with the first time of the first satellite, where it wouldn't converge. This is theorized to be due to the fact that the ground stations were too close together to provide far enough points to converge.

2.3 Position Vectors

The position vector was found by using a transformation matrix to change the coordinates from an ECEF frame to an IJK frame. This was done by taking the inverse of the R_z transformation matrix and then multiplying that to the ECEF vector. The resultant is the IJK vector. This is because the IJK frame and the ECEF frame share the same z axis so the transformation was simple.

2.4 Solving the Lambert Problem

2.5 Pseudoranges

3 Conclusion

3.1 Results

We were unable to get results due to the issue with trilateration of the first satellite time value.

3.2 Sources of Error

During the analysis, we had trouble getting the Trilateration Code for G32 to Converge at t1. The Trilateration code did converge for G32 at t2 and G10 at both t1 and t2. However, the position vectors we got out of the trilateration code were off from the position vectors by each ground site's sp3 files. We tested the trilateration code using an example from the textbook (Page 146) and Assignment 7 by inputting the given ranges and reference positions into the trilateration code and comparing the output of the code with the correct answers to the example problem and the homework. The output of the code matched the textbook and assignment answers, which led us to conclude that the code was written correctly, and is not the source of the error.

The error came from the chosen ground stations being too close to each other. When the ground stations were being selected, they were selected in a way where all three ground stations were as far away from each other as possible, but within 250 km of each other so that all three stations can receive the GNSS signal simultaneously. This Ground Station Selection method ended up becoming a source of error in our results. Trilateration works best when the reference locations are spread very far apart.

3.3 Limitations

One limitation of our analysis is that the trilateration code didn't include the transmitter clock error. This would have made the analysis much more accurate. GNSS trilateration is different from normal trilateration because GNSS trilateration includes the transmitter clock error. Including the transmitter clock error makes up for the time dilation GPS satellites go through in their orbits. (according to Special and General Relativity)

The analysis was also limited by the constrained range of dates given in the project. (January to October 2019) It was said before that the orbit of the GNSS satellite will change over time due to Drag and J2 Perturbations. Since the goal of the project is to measure the orbit of the GNSS satellite, it makes sense to get the most recent data from the ground stations, so that the results of the analysis (the estimated orbital elements of the chosen GNSS satellite) will be as up-to-date and accurate as possible.

If there is one thing about the project that can be changed to improve the accuracy of the results (and rid the analysis of this limitation), it would be to get rid of the constrained range of dates, so that students could pick a date from January 2019 to any day of 2019 where GNSS data is available. This will allow students to perform the analysis on more recent, up-to-date data and return more accurate results.

```

B Group Work Distribution

B.1 Tyler Chotoo

- List of the five digit SDC numbers for all the NAVSTAR satellites.
- Found the satellites corresponding to our chosen PRN.
- Did part five of the analysis.
- Contributed to writing the report in the work done section.
- Attempted to find results

B.2 Abubakr Hamid

-

B.3 Richard Quarles

- Ground Site Determination (using the CORS Map)
- Data Collection from the CORS Website
- Pseudo-range and Ground Site ECEF Determination (using the Observation files)
- Spreadsheet
- Wrote the Overview and 2.1.1, created the Results Tables, and contributed to the Sources of Error subsection of the report, as well as the Limitations subsection.

B.4 Blaire Weinberg
